# Chapter 1

## Introduction

**Name:** Bill

- Beginner
- Intermediate
- Learning
- Language

**Purpose:** It is a general purpose statically typed, with dynamic types, easy to learn and use language.

**Key uses:**

- Learning basic level programming.
- Pursuing enthusiast programming.

**Features:**

- portable
- a variety of useful data types
- extend-able data types
- simple to use
- constants
- ease of static typing
- strong static typing

Hello World

"Hello World" is traditionally the first program one writes in a new language. That makes it a good starting point.

```
#!/usr/bin/env bill

# hello.bill
# aka hello world

fun main():no_value
{
    writeln("Hello World")
    exit // defaults to 0
}
```

hello.bill

Of course, the first few lines are unnecessary. However, declaring a main function is required. For details, on that, in chapter 6 ([Functions](#)).

To compile and run:

```
prompt> bill hello.bill
```

If your operating system supports shebangs, the following will work:

```
prompt> hello.bill
```

## 1.1 Reserved Words

Here is a list of Reserved Words:

break	exit loop	See <a href="#">Loops</a>
continue	skip to next iteration	See <a href="#">Loops</a>
else	default condition	See <a href="#">Loops</a>
elsif	subsequent condition	See <a href="#">Loops</a>
exit	end program (possible exit value)	See below.
if	condition	See <a href="#">Loops</a>
return	end a function (possible return value)	See <a href="#">Functions</a>
try	begin try block	See <a href="#">Exceptions</a>

With exit, you can use any positive int64 value. However, 0 (default) generally represents a good run. Typically, a problem is designated by 1.

Next: [Types](#)

## Chapter 2

# Types

## Types

### Types

Every form of data is a type. By extension, the same is true for functions. Built in types:

- null
- boolean
- int8
- int64
- float64
- string
- array
- vector
- set
- tuple
- dictionary

## 2.1 Integers

All integers are signed. See [Unsigned](#) for more information.

There are two integer types:

- int8 is 8 bit. (-128 to +127)
- int64 is 64 bit. (-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807)

See <https://en.cppreference.com/w/cpp/language/types>

*Tip:* Only use int8 for space conserving situations, provided all values will always fall within limits. Else, use int64. Don't trust "There's no reason for it to go beyond limits." It must be **impossible** to exceed limits or, it's only a matter of time.

### 2.1.1 Unsigned

Why no unsigned integers? Here is a great answer:

<https://blog.robertelder.org/signed-or-unsigned-part-2/>

## 2.2 Floats

The float 64 offers the same specs as c++ double.

## 2.3 Boolean

## 2.4 Strings

## 2.5 Null

## 2.6 Others

For more information, please see [Containers](#).

### 3.2 Concatenation

#### 3.2.1 Operators

Next: [Containers](#)

## Chapter 4

# Containers

### Containers

Containers can hold multiple values.

## 4.1 Arrays

## 4.2 Vectors

Vectors, which are similar to lists, are sequences of data.

```
# vector.bill
# for vector samples

/* @fn      main
 * @brief   vectors
 */
fun main():no_value
{
    var primaries:vector
    primaries = ["red", "yellow", "blue"]
    println(primaries)      // prints ["red", "yellow", "blue"]

    var secondaries:vector = ["orange", "green", "purple"]
    println(primaries[1])   // prints green
    println(primaries[:2])  // prints ["orange", "green"]
    println(primaries[1:])  // prints ["green", "purple"]
    println(primaries[2:3]) // prints ["green", "purple"]
    // println(primaries[-1]) // prints purple
}
```

## 4.3 Sets

Sets are based on the mathematical sets. See [sets](#) Note: sets are unordered. Accessing them will result in random ordering.

```
# set.bill
# for set samples

/* @fn      main
 * @brief   sets
 */
fun main():no_value
{
    var primaries:set
    primaries = {"red", "yellow", "blue"}
    println(primaries)          // prints {"red", "yellow", "blue"}

    var colors:set = {"red", "yellow"}

    // check subsets
    println(primaries < colors) // prints false
    println(colors < primaries) // prints true

    // check supersets
    println(primaries > colors) // prints true
    println(colors > primaries) // prints false

    // add more later
}
```

## 4.4 Tuples

## 4.5 Dictionaries

## 4.6 Others

Next: [Flow Control](#)

# Chapter 5

## Flow Control

### Flow Control

Flow control is about conditions.

### 5.1 Conditions

Conditions amount to Bool boolean states. E.G.:

- $x > y$
- $i == 12$
- $2 + 2 == 4$
- $\text{fruit} == \text{"apple"}$
- etc (assuming etc is a boolean variable...)

Therefore the usual boolean rules apply here.

#### 5.1.1 Conditionals

If

```
# if Conditional Example

fun main():no_value
{
    if true:
    {
        println(8)
    }
}
```

Else

```
# if - else Conditional Example

fun main():no_value
{
    if true:
    {
        writeln(8)
    }
    else:
    {
        writeln(2 + 3)
    }
}
```

## Elsif

```
# Full Conditional Example

fun main():no_value
{
    if true:
    {
        writeln(8)
    }
    elsif false:
    {
        writeln(7, 9)
    }
    else:
    {
        writeln(2 + 3)
    }
}
```

## 5.1.2 Loops

### While

```
# whileloop.bill
# while loop syntax sample

fun main(argv):int8
{
    while true:
    {
        # This is the loop that never ends.
    }

    while 1 > 3:
    {
        # This loop is skipped.
    }

    var i:int8 = 0
    while i < argv[1]:
    {
        writeln(i)
        i ++
    }
}
```

### For

```
# forloop.bill
# for loop syntax sample

/* @fn      main
 * @brief   forloops
 */
fun main():no_value
{
    for var i:int64 = 0 to 10:
    {
        println(i)
    }

    for (var i:int64 = 0; i < 1):
    {
        println(i)
    }

    for (var i:float64 = 0; i < 1; i += .03):
    {
        println(i)
    }

    // foreach(variable, sequence)
    foreach(var primary:string, ["red", "yellow", "blue"]):
    {
        println(primary)
    }
}
```

## 5.2 Traversal

Next: [Functions](#)

## Chapter 6

# Functions

### Functions

Encapsulating repeatable steps, is how we make programming easier.

## 6.1 Calling a Function

## 6.2 Declaring a Function

As seen in the Introduction, we have simple declarations.

```
#!/usr/bin/env bill

# hello.bill
# aka hello world

fun main():no_value
{
    writeln("Hello World")
    exit // defaults to 0
}
```

hello.bill

The function definition line should look familiar. The "fun" reserved word declares a function.

After the ":" is the function return type. However, in this case "no\_value" indicates there is no return of any kind.

A common practice of statically typed languages is to declare the type "void," which is similar.

## 6.3 Return

## 6.4 Used in Expressions

## 6.5 Built-in

Here is a list of built-in functions:

<code>catch()</code>	catch exception
<code>throw()</code>	throw exception
<code>toFloat()</code>	convert to float
<code>toInt()</code>	convert to integer
<code>toString()</code>	convert to string
<code>toTuple()</code>	convert to tuple
<code>type()</code>	get an object's type
<code>write()</code>	print (without newline)
<code>writeln()</code>	print (with newline)

Next: [Exceptions](#)

## Chapter 7

# Exceptions

### Exceptions

As we all know, "Things don't always go according to plan." Hence programmers need to account for this, with exception handling.

## 7.1 Throw

Let's just throw this out.

```
# Throw!

fun main():no_value
{
    throw("Something happened!")
}
```

## 7.2 Try

First a simple example.

```
# Try something!

fun main():no_value
{
    try:
    {
        println(8)
    }
    catch():
    {
        throw("What happened?")
    }
}
```

This is ok, if there is no concern over "What went wrong?"

## 7.3 Catch

Now, let's catch the exception.

```
# Try...catch!

fun main():no_value
{
    try:
    {
        println(8)
    }
    catch(exception):
    {
        throw(exception + " happened!")
    }
}
```

However, this only catches a specific exception.

```
# Try...indexError!

fun main():no_value
{
    try:
    {
        println(8)
    }
    catch(indexError):                // Specific exception caught.
    {
        throw("Index out of range.") // Specific exception handled.
    }
    catch(exception):                // Unknown exception caught.
    {
        throw(exception + " happened!") // Unknown exception handled.
    }
}
```

By daisy chaining catches, we can fine tune the response.

Next: [Style](#)

# Chapter 8

## Style

### Style

Code style can be a matter of choice...

However, consistency means readability. As such, here are conventions used throughout this documentation.

### 8.1 Comments

Possible comment types:

```
# This is a comment type recommended for shebangs.
// This is the recommended end-of-line comment.
/* This type of comment is recommended for documentation blocks. */

// or

/* myfunction
 * Demo an operation
 */
```

### 8.2 Statements

### 8.3 Blocks

```
Declaration:    // if, while, etc...
{
    // Code here.
}
```
